Background

- cCBT is computer-guided self-help based on cognitive behaviour therapy (CBT). It allows patients to work through a therapy program by themselves without major help from a professional.
- Computer-aided self-help has been introduced as a way of improving the convenient supply of effective CBT.
- cCBT systems have been developed for problems such as phobia/panic and obsessive-compulsive disorders, depression, post-traumatic stress disorder, general anxiety, smoking, bulimia/binge-eating, headaches.
- cCBT facilitates the disclosure of sensitive information and is a convenient de-stigmatising approach to psychological help.
- cCBT systems lack a clinician’s intuition and some patients prefer a live therapist, though others prefer cCBT.

Evidence-base for cCBT

- Certain cCBT systems effectively improved some problems with outcomes resembling those for face-to-face therapy, while other systems yielded little or no benefit to patients.
- Some cCBT systems cost less to use for treating a given population than it would cost to train and employ enough therapists to treat the same population with similar effectiveness.
- Patients are more likely to take up cCBT if they expect it to be helpful for their problems.
- Better education, more improvement and greater satisfaction are associated with higher completion rates.
- Although patients with more severe symptoms at baseline benefited more from cCBT, they were less likely to adhere to it.
- GP-referrals improved more with cCBT than referrals from mental health professionals.

Role of the physician and brief ‘human’ support in cCBT

- Brief human support increased adherence to and completion of cCBT and improved clinical outcome.
- Regular brief support scheduled by a clinician made cCBT for obsessive-compulsive disorder more effective than did ad-hoc support at the patient’s request.
- Support can be personalised or standardised and can be given by phone, face-to-face, email, SMS (short messaging service), or by post.
- Across cCBT systems, duration of brief personal support varies from none at all to several hours given weekly, fortnightly or at other specific time-points. For NICE-recommended cCBT systems support is about one hour spread over three months.
- Staff giving brief support could be any of a wide variety of staff who have, as a pretend patient, worked completely through the cCBT system whose users they will support, and who have had brief training in answering common questions.

Using cCBT in routine clinical practice

- The National Institute for Health and Care Excellence (NICE, 2006) recommends the use of two commercial cCBT systems: FearFighter for phobia/panic and Beating the Blues for mild-moderate depression.
- Open-access free-of-charge cCBT systems are available on the internet but support is needed as an adjunct to using these systems to reduce attrition.
- Suitability criteria for cCBT reflect criteria for therapist-delivered CBT: i.e. current symptoms, no suicide plans, no excessive alcohol, drug or sedative, no serious physical or mental illness that might worsen with some forms of CBT, an age-11 ability to read or better.
- Therapist-delivered CBT is more appropriate for patients who are at high risk of suicide or deliberate self-harm, have specific problems for which cCBT has no proof of effect e.g. PTSD, health anxiety, severe depression, and strong preference to see a therapist.
- Screening for suitability can be brief and be done with a self-rated questionnaire by pen-and-paper or electronically.
• cCBT is best as an early step in primary care but can also help patients on therapists’ waiting lists or in general psychiatric services.
• Set-up, maintenance and population-wide availability of cCBT requires it to be efficiently integrated into existing services.
